#### **Outline**

- Case study: Modeling travel mode choices
- Logistic regression
- Generalized linear models (GLMs)
- Hierarchical models

#### Modeling travel mode choices

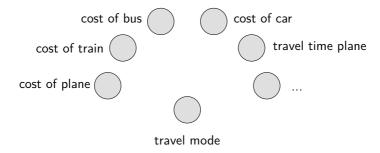

- Travel diary data
  - 394 survey observations from 80 individuals
  - 4 travel modes: plane, train, bus or car
- Goal: model user mode choices
- Trip attributes (features):
  - Terminal waiting time
  - Cost (dollars)
  - Travel time (minutes)
  - Household income
  - Traveling group size
- Some possible applications:
  - Understanding people's choices
  - Developing pricing policies
  - Incentivising mode change
  - Suggesting car pooling

# Modeling travel mode choices (cont'd)

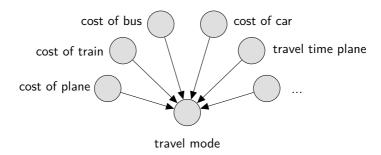

• Let's start thinking about the graphical model...

# Modeling travel mode choices (cont'd)

Let's start thinking about the graphical model...

- What distribution should we assign to the "travel mode" variable?
  - Travel mode is a discrete variable!
  - We are now in a classification setting
- How should we model the dependency of the travel mode on the other variables?

#### Discrete output variables

• We can represent our model for the entire dataset compactly as:

N is the number of trips in the dataset  $y_n$  is the travel mode of the  $n^{th}$  trip in the dataset  $\mathbf{x}_n$  is a vector with {cost of plane, cost of train, ...} for trip n

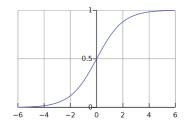

- Looks familiar?
- But how should we model the dependency of  $y_n$  on  $\mathbf{x}_n$ ?
  - We can assume a parameterized linear relationship:  $y_n = \beta^\mathsf{T} \mathbf{x}_n$
  - But  $y_n \notin \mathbb{R}!$  Instead:  $y_n \in \{\text{plane, train, bus, car}\}$

## Binary logistic regression

- Consider the binary case:  $y_n \in \{0, 1\}$
- ullet We need a function that maps from  $\mathbb R$  to [0,1]
- A sigmoid ("S"-shaped) function does precisely that!
- E.g. logistic sigmoid:

$$\begin{aligned} \mathsf{Sigmoid}(z) &= \frac{1}{1 + e^{-z}} \\ &= \frac{e^z}{e^z + 1} \end{aligned}$$

- ullet We can define  $z_n = oldsymbol{eta}^\mathsf{T} \mathbf{x}_n$
- The value of Sigmoid $(z_n)$  can then be interpreted as the probability of the  $n^{th}$  instance belonging to class "1":  $p(y_n=1)$
- ullet The probability of class "0" is simply:  $p(y_n=0)=1-\mathsf{Sigmoid}(z_n)$

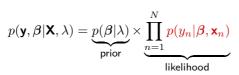

#### Binary logistic regression as a graphical model

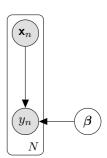

• We have a dataset  $\mathcal{D}$  consisting of N observations of the targets  $y_n \in \{0,1\}$ which depend on their corresponding explanatory variables  $\mathbf{x}_n$ 

$$\mathcal{D} = \{\mathbf{x}_n, y_n\}_{n=1}^N$$

- Generative process
  - (1) Draw coefficients  $\beta \sim \mathcal{N}(\beta|\mathbf{0},\lambda\mathbf{I})$  (2) For each feature vector  $\mathbf{x}_n$
  - - (a) Draw class  $y_n \sim \text{Bernoulli}(y_n|\text{Sigmoid}(\beta^\mathsf{T} \mathbf{x}_n))$
- Joint probability distribution factorizes as

where  $\mathbf{y} = \{y_n\}_{n=1}^N$ ,  $\mathbf{X} = \{\mathbf{x}_n\}_{n=1}^N$  and  $\boldsymbol{\beta}$  are the model parameters.

#### Multi-class logistic regression

What if we have multiple classes? (like in our mode choice example...)

$$y_n \in \{\text{plane, train, bus, car}\}$$

• The generalization of the logistic sigmoid to multiple outputs is the **softmax**:

$$\mathsf{Softmax}(\mathbf{x}_n, \boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_C)_c = \frac{\exp(\boldsymbol{\beta}_c^\mathsf{T} \mathbf{x}_n)}{\sum_k \exp(\boldsymbol{\beta}_k^\mathsf{T} \mathbf{x}_n)}, \quad \mathsf{for} \, c \in \{1, \dots, C\}$$

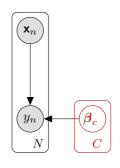

where C denotes the number of classes

- ullet Notice that we now need C vectors of parameters:  $\{eta_1,\ldotseta_C\}$
- The output of the softmax is then a vector  $\eta = [\eta_1, \dots, \eta_C]$  where  $\eta_c = \mathsf{Softmax}(\mathbf{x}_n, \boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_C)_c$
- $\bullet$  The value of  $\eta_c$  can be interpreted as the probability of the  $n^{th}$  instance belonging to class c
- ullet The softmax ensures that  $\sum_{c=1}^C \eta_c = 1$

# Multi-class logistic regression as a graphical model

- Updated graphical model
- Generative process
  - (1) For each class  $c \in \{1, \dots, C\}$ 
    - (a) Draw coefficients  $\boldsymbol{\beta}_c \sim \mathcal{N}(\boldsymbol{\beta}_c | \mathbf{0}, \lambda \mathbf{I})$
  - (2) For each feature vector  $\mathbf{x}_n$ 
    - (a) Draw class  $y_n \sim \mathsf{Multinomial}(y_n|\mathsf{Softmax}(\mathbf{x}_n, \boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_C))$

• Joint probability distribution factorizes as

$$p(\mathbf{y}, \boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_C | \mathbf{X}, \boldsymbol{\lambda}) = \underbrace{\left(\prod_{c=1}^C p(\boldsymbol{\beta}_c | \boldsymbol{\lambda})\right)}_{\text{prior}} \times \underbrace{\prod_{n=1}^N p(y_n | \mathbf{x}_n, \boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_C)}_{\text{likelihood}}$$

#### Inference

- **Goal:** compute **posterior** distribution on  $\beta_1, \ldots, \beta_C$
- Following Bayes' theorem

$$\underbrace{p(\boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_C | \mathbf{y}, \mathbf{X}, \lambda)}_{\text{posterior}} \propto \underbrace{\left(\prod_{c=1}^C \mathcal{N}(\boldsymbol{\beta}_c | \mathbf{0}, \lambda \mathbf{I})\right)}_{\text{prior}} \times \underbrace{\prod_{n=1}^N \text{Multinomial}(y_n | \text{Softmax}(\mathbf{x}_n, \boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_C))}_{\text{likelihood}}$$

- Exact inference is intractable
- Must resort to approximate inference methods
- Not a problem for Stan :-)

#### Playtime!

- Ancestral sampling from multi-class logistic regression model
  - See "Logistic regression Ancestral sampling.ipynb" notebook
  - Expected duration: 15 minutes
- Bayesian multi-class logistic regression model of travel mode choices
  - See "Travel mode choice Logistic regression.ipynb" notebook
  - Expected duration: 1 hour

#### Generalized linear models (GLMs)

- So far we saw a series of linear models
  - Linear regression
  - Poisson regression
  - Logistic regression
- ullet The parameters eta enter the distribution of  $y_n$  through a linear combination of  ${f x}_n$
- The difference is in the distribution of the response
  - Gaussian for linear regression
  - Poisson for poisson regression
  - Bernoulli for binary logistic regression
  - Multinomial for multi-class logistic regression
- In other words, we just changed the form of the likelihood!
- All belong to a general class of models called generalized linear models
  - The idea is to use a general exponential family for the response distribution
  - Can handle real, binary, categorical, positive real, positive integer and ordinal responses

#### **Probit regression**

- Another example of a generalized linear model
- Very similar to logistic regression
- But uses a different link function: probit instead of the logistic sigmoid
- ullet Probit function  $\Phi$  is the CDF of the standard Gaussian distribution  $\mathcal{N}(0,1)$

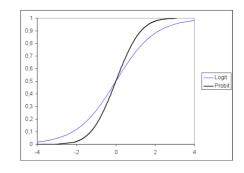

$$\Phi(z) = \int_{-\infty}^{z} \mathcal{N}(t|0,1) dt$$
$$= \frac{1}{2} \left[ 1 + \operatorname{erf}\left(\frac{x}{\sqrt{2}}\right) \right]$$

where  $erf(\cdot)$  is a special function

- (1) Draw coefficients  $\beta \sim \mathcal{N}(\beta | \mathbf{0}, \lambda \mathbf{I})$
- (2) For each feature vector  $\mathbf{x}_n$

(a) Draw class 
$$y_n \sim \text{Bernoulli}(y_n | \Phi(\boldsymbol{\beta}^\mathsf{T} \mathbf{x}_n))$$

# Playtime!

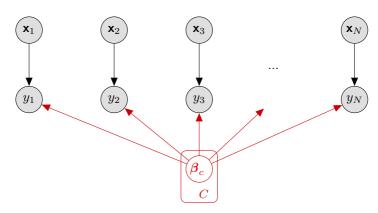

- Probit regression vs logistic regression model
- See "Travel mode choice Probit regression.ipynb" notebook

## Going back to our travel mode choice case study...

Let's revise the modeling assumptions that we made

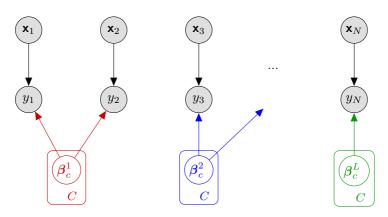

- Single set of parameters  $\{\beta_1, \dots, \beta_C\}$  for **all** the observations
  - This corresponds to saying that all individuals give the same importance (weight) to all the features (e.g. travel time) and have the same biases!

## Going back to our travel mode choice case study...

• Alternatively, we can assign each individual his/her own parameters

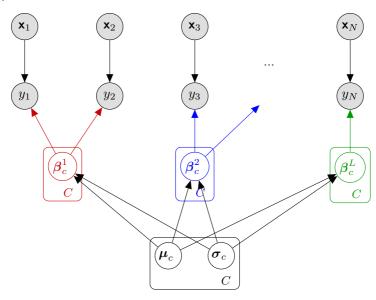

- ullet Each individual  $l \in \{1,\dots,L\}$  gets his/her own set of parameters  $\{m{eta}_1^l,\dots,m{eta}_C^l\}$ 
  - Allows to capture personalized preferences and biases
  - But can lead to terrible overfitting! (more parameters than observations)

## Going back to our travel mode choice case study...

• A compromise between the two: hierarchical models

#### Hierarchical models

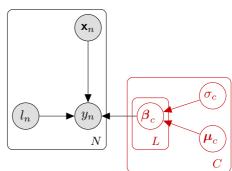

- Assume the data is grouped into L distinct levels (or groups)
  - In our travel mode choice example, levels correspond to e.g. individuals
- ullet Data from each level l gets its own set of parameters
- ullet Shared global prior ("hyper-prior") ties together the parameters of each level l
- A compromise between two extremes:
  - On one extreme, each level l gets its own set of parameters (no pooling)
  - On the other extreme, all the observations share a single set of parameters (complete pooling)
- The degree of pooling is determined by the data and the specified priors

#### Note

This concept can also be applied to other types of models! E.g. linear regression, poisson regression, etc.

# Hierarchical logistic regression model

- Probabilistic graphical model
- $l_n$  is used to denote the level (or group) that the  $n^{th}$ observation belongs to

Joint probability distribution:

$$p(\mathbf{y}, \mathbf{B}^1, \dots, \mathbf{B}^L, \boldsymbol{\mu}_1, \dots, \boldsymbol{\mu}_C, \sigma_1, \dots, \sigma_C | \mathbf{X}, \mathbf{I}) \\ = \underbrace{\left(\prod_{c=1}^C p(\boldsymbol{\mu}_c) \, p(\sigma_c) \prod_{l=1}^L p(\boldsymbol{\beta}_c^l | \boldsymbol{\mu}_c, \sigma_c)\right)}_{\text{hierarchical prior}} \times \underbrace{\prod_{n=1}^N p(y_n | \mathbf{x}_n, l_n, \mathbf{B}^1, \dots, \mathbf{B}^L)}_{\text{likelihood}}$$

where we defined  $\mathbf{B}^l = \{oldsymbol{eta}_1^l, \dots, oldsymbol{eta}_C^l\}$ 

## Hierarchical logistic regression model

Generative process

- (1) For each class  $c \in \{1, \dots, C\}$ 
  - (a) Draw global mean parameters  $m{\mu}_c \sim \mathcal{N}(m{\mu}_c | \mathbf{0}, \lambda \mathbf{I})$
  - (b) Draw global variance parameter  $\sigma_c \sim \mathcal{N}(\sigma_c|0,\tau)$
  - (c) For each level  $l \in \{1, \dots, L\}$ 
    - (a) Draw coefficients  $\pmb{\beta}_c^l \sim \mathcal{N}(\pmb{\beta}_c^l|\pmb{\mu}_c,e^{\sigma_c}\mathbf{I})$
- (2) For each feature vector  $\mathbf{x}_n$ 
  - (a) Draw class  $y_n \sim \mathsf{Multinomial}(y_n|\mathsf{Softmax}(\mathbf{x}_n, \boldsymbol{\beta}_1^{l_n}, \dots, \boldsymbol{\beta}_C^{l_n}))$
- There are many variants of this that we can consider
  - ullet A vector of variances  $oldsymbol{\sigma}_c$  rather than a single variance  $\sigma_c$  for all the features
  - ullet Different prior distributions on  $oldsymbol{\mu}_c$ ,  $\sigma_c$  and even  $oldsymbol{eta}_c^l$
  - ullet Hierarchical prior only on the biases (intercepts) rather than on all the  $oldsymbol{eta}_c$
  - More levels, etc.

#### Playtime!

- Bayesian hierarchical multi-class logistic regression model of travel mode choices
- Each individual has his/her own bias towards certain travel modes
- See "Travel mode choice Hierarchical models.ipynb" notebook
- Expected duration: 1 hour
